(54) Title: **VLA-4 INHIBITOR COMPOUNDS**

(57) Abstract: Compounds that selectively inhibit the binding of ligands to  $\alpha 4 \beta 1$  integrin (VLA-4) and methods for their preparation are disclosed. In one embodiment, compounds of the invention are represented by formula (I). As selective inhibitors of VLA-4 mediated cell adhesion, compounds of the present invention are useful in the treatment of conditions associated with such adhesion, including, but not limited to, such conditions as inflammatory and autoimmune responses, diabetes, asthma, psoriasis, inflammatory bowel disease, transplantation rejection, and tumor metastasis. Also disclosed are methods of inhibiting VLA-4 mediated cell adhesion and methods of treating conditions associated with LA-4 mediated cell adhesion.

## VLA-4 INHIBITOR COMPOUNDS

FIELD OF THE INVENTION

The present invention relates to compounds that selectively inhibit the binding of ligands to the adhesion receptor,  $\alpha_4\beta_1$  integrin, also known as VLA-4. Compounds of the present invention are useful in the treatment and prevention of pathologies associated with VLA-4 mediated cell adhesion, such as inflammatory and autoimmune diseases, and tumor metastasis.

BACKGROUND OF THE INVENTION

A primary feature of such pathologies as inflammation and autoimmune diseases is the accumulation of activated leukocytes in affected tissues. The process by which leukocytes transmigrate from the circulation at a site of inflammation involves a cascade of interactions that can be divided into four major steps: tethering and rolling, activation, firm adhesion, and transmigration (Springer, T., Ann. Rev. Physiol., 57:827 (1995)). Initially, leukocytes are lightly tethered to the endothelium and roll along its surface. This is followed by cell activation, mediated by soluble chemotactic stimuli, which initiates the development of a firmer bond between individual leukocytes and endothelial cells. The firm bond then results in the successful adhesion and transmigration of the leukocytes through endothelial cell junctions. The steps occur in series and each is essential for transmigration to occur. This also means that transmigration can be modulated at each step, thus providing a number of potential targets for pharmacological inhibition.

The receptors involved in leukocyte migration have, to a large extent, been characterized as belonging to particular cell adhesion molecule families (Carlos and Harlan, Blood, 84:2068 (1994)). The initial attachment and rolling step is mediated by a family of adhesion receptors referred to as selectins. Firm adhesion is mediated by interaction of leukocyte surface integrins with molecules of the immunoglobulin superfamily expressed on the surface of the endothelium. Both integrins and the immunoglobulin-type adhesion molecules are also primarily involved in leukocyte transmigration. After transmigration, the leukocytes rely on integrins to traverse through the extracellular matrix and remain at the site of inflammation.

Integrins are a large family of heterodimeric glycoproteins composed of two noncovalently associated subunits,  $\alpha$  and  $\beta$  (Hynes, R., Cell, 69:11 (1992)). There are at least 16 different  $\alpha$  subunits ( $\alpha_1$ - $\alpha_9$ ,  $\alpha_L$ ,  $\alpha_M$ ,  $\alpha_D$ ,  $\alpha_X$ ,  $\alpha_E$ ,  $\alpha_{IIb}$ ,  $\alpha_v$ ) and at least 9 different  $\beta$  ( $\beta_1$ - $\beta_9$ )

subunits. Integrins are divided into sub-families, based upon the  $\beta$  subunit. Leukocytes express a number of different integrins, including  $\alpha_4\beta_1$ ,  $\alpha_5\beta_1$ ,  $\alpha_6\beta_1$ ,  $\alpha_4\beta_7$ ,  $\alpha_L\beta_2$ ,  $\alpha_X\beta_2$ , and  $\alpha_V\beta_3$ .

$\alpha_4\beta_1$  integrin, also known as very late antigen-4 (VLA-4) or CD49d/CD29, is expressed on monocytes, lymphocytes, eosinophils, and basophils, all of which are key effector cells in various inflammatory disorders (Helmer, M., Ann. Rev. Immunol., 8:365 (1990)).  $\alpha_4\beta_1$  integrin serves as a receptor for vascular cell adhesion molecule-1 (VCAM-1), as well as to the extracellular protein fibronectin (FN) (Elices *et al.*, Cell, 60:577 (1990)). Anti-inflammatory effects and delayed disease progression have been demonstrated after *in vivo* monoclonal antibody blockade of the  $\alpha_4\beta_1$ /VCAM-1 pathway (Lobb *et al.*, J. Clin. Invest., 94:1722-28 (1994)). In a guinea pig model of pulmonary inflammation, anti- $\alpha_4$  inhibited both antigen-induced bronchial hyperreactivity and leukocyte recruitment in bronchoalveolar lavage fluid (Pretolani *et al.*, J. Exp. Med., 180:795 (1994)). Antibodies to  $\alpha_4$  or VCAM-1, prevented antigen-induced eosinophil infiltration of the mouse trachea (Nakajima *et al.*, J. Exp. Med., 179:1145 (1994)).  $\alpha_4$  or VCAM-1 monoclonal antibody treatment also delayed or prevented cutaneous delayed hypersensitivity response in mice and monkeys (Chisholm *et al.*, Eur. J. Immunol., 23:682 (1993); Silber *et al.*, J. Clin. Invest., 93:1554 (1993); cardiac allograft rejection in mice, accompanied by specific immunosuppression (Isobe *et al.*, J. Immunol., 153:5810 (1994); graft-versus-host disease in mice after bone marrow transfer (Yang *et al.*, Proc. Natl. Acad. Sci. USA, 90:10494, (1993); and experimental autoimmune encephalomyelitis in rats and mice (Yednock *et al.*, Nature, 356:63 (1992); Baron *et al.*, J. Exp. Med., 177:57 (1993)).

Rational drug design studies have produced soluble VCAM-Ig fusion protein containing the two N-terminal domains of human VCAM-1 fused to a human IgG1 constant region. *In vivo* administration of the fusion protein significantly delays the onset of adoptively transferred autoimmune diabetes in nonobese diabetic mice (Jakubowski *et al.*, J. Immunol., 155:938 (1995)). Another approach has used three-dimensional crystallographic structures of VCAM-1 fragments to synthesize cyclic peptide antagonists that closely mimicked the  $\alpha_4$  integrin binding loop in domain 1 of VCAM-1. Synthetic VCAM-1 peptide CQIDSPC, was able to inhibit the adhesion of VLA-4-expressing cells to purified VCAM-1 (Wang *et al.*, Proc. Natl. Acad. Sci. USA, 92:5714 (1995)).

An additional strategy is to block the binding of  $\alpha_4\beta_1$  to its other counter receptor, that is, an alternatively spliced region of fibronectin containing the connecting segment-1 (CS-1) motif

(E.A. Wayner, *J. Cell. Biol.*, 116:489 (1992)). A synthetic CS-1 tetrapeptide (phenylacetic acid-Leu-Asp-Phe-d-Pro-amide) inhibited VLA-4-mediated lymphocyte adherence *in vitro* and reduced accelerated coronary arteriopathy in rabbit cardiac allografts (Molossi *et al.*, *J. Clin. Invest.*, 95:2601 (1995)). Each of these studies provide evidence that selective inhibition of  $\alpha_4\beta_1$ /VCAM-1 mediated adhesion is a proven strategy in the treatment of autoimmune and allergic inflammatory diseases.

Moreover, while United States Patent 5,821,231 and PCT Applications WO 96/22966, WO 97/03094, WO 98/04247 and WO 98/04913 describe compounds exhibiting VLA-4 inhibitory activity in *in vitro* binding assays, none of the described compounds have exhibited efficacy in oral administration.

Accordingly, despite these advances, there remains a need for small, non-peptidic, specific inhibitors of VLA-4 dependent cell adhesion that are orally bioavailable and that are suitable for the long-term treatment of chronic inflammatory diseases and other pathologies associated with leukocyte migration and adhesion.

## SUMMARY OF THE INVENTION

The compounds of the present invention selectively inhibit the binding of ligands to  $\alpha_4\beta_1$  and therefore, are useful for inhibition, prevention and suppression of VLA-4-mediated cell adhesion and the pathologies associated with that adhesion, such as, for example, inflammation, asthma, arthritis, diabetes, autoimmune responses, multiple sclerosis, psoriasis, transplantation rejection, and tumor metastasis.

The principles of the present invention also encompass prodrugs in the scope of Formula I, and compounds representative thereof include those wherein R<sup>5</sup> or R<sup>8</sup> is a lower alkoxy group, and those wherein R<sup>10</sup> or R<sup>19</sup> is a lower alkoxy carbonyl group.

The principles of the present invention also provide a method for inhibiting cell adhesion, and in particular, VLA-4 mediated cell adhesion at  $\alpha 4\beta 1$  receptor sites in a mammal, wherein the method comprises administering an effective amount of a compound represented by Formula I. As used herein, inhibiting cell adhesion is intended to include inhibiting, suppressing and preventing VLA-4 mediated cell adhesion-associated conditions, including but not limited to, inflammation and cell adhesion-associated immune or autoimmune responses.

The principles of the present invention therefore also provide a method of treating a condition associated with VLA-4 mediated cell adhesion, wherein the method comprises administering to a mammal in need of such treatment, an effective amount of a compound represented by Formula I. Such conditions include for example, but are not limited to, inflammatory and autoimmune responses, diabetes, asthma, arthritis, psoriasis, multiple sclerosis, inflammatory bowel disease, transplantation rejection, and tumor metastasis. As used herein, "treatment" of a mammal is intended to include prophylaxis as well.

The compounds of the present invention may be administered as a monotherapy, or in combination with antiinflammatory or immunosuppressive agents. Such combination therapies can involve the administration of the various pharmaceuticals as a single dosage form or as multiple dosage forms administered at the same time or at different times.

5           Any suitable route of administration may be employed for providing a patient with an effective amount of a compound of the present invention. Suitable routes of administration may include, for example, oral, rectal, nasal, buccal, parenteral (such as, intravenous, intrathecal, subcutaneous, intramuscular, intrasternal, intrahepatic, intralesional, intracranial, intra-articular, and intra-synovial), transdermal (such as, for example, patches), and the like. Due to their ease of  
10 administration, oral dosage forms, such as, for example, tablets, troches, dispersions, suspensions, solutions, capsules, soft gelatin capsules, and the like, may be preferred. Administration may also be by controlled or sustained release means and delivery devices. Methods for the preparation of such dosage forms are well known in the art.

          Pharmaceutical compositions incorporating compounds of the present invention may  
15 include excipients, a pharmaceutically acceptable carrier, in addition to other therapeutic ingredients. Excipients such as starches, sugars, microcrystalline cellulose, diluents, lubricants, binders, coloring agents, flavoring agents, granulating agents, disintegrating agents, and the like may be appropriate depending upon the route of administration. Because of their ease of administration, tablets and capsules represent the most advantageous oral dosage unit forms. If  
20 desired, tablets may be coated by standard aqueous or nonaqueous techniques.

          The compounds of the present invention may be used in the form of pharmaceutically acceptable salts derived from inorganic or organic bases. Suitable pharmaceutically acceptable base addition salts include, but are not limited to, ammonium salts, alkali metal salts, metallic salts made from aluminum, calcium, lithium, magnesium, potassium, sodium and zinc, organic salts  
25 made from chloroprocaine, choline, *N,N'*-dibenzylethylenediamine, dicyclohexylamine, diethanolamine, ethylenediamine, lysine, meglumine (*N*-methylglucamine) and procaine, as well as salts with amino acids, such as arginine, lysine, and so forth.

          Where the compounds of the invention have a basic moiety, such as an amino group, the compounds may be used in the form of pharmaceutically acceptable non-toxic organic or inorganic  
30 acids. Such acids include acetic, benzenesulfonic, benzoic, camphorsulfonic, citric,

ethanesulfonic, methanesulfonic, fumaric, gluconic, glutamic, hydrobromic, hydrochloric, lactic, maleic, malic, mandelic, nitric, pamoic, pantothenic, phosphoric, succinic, sulfuric, tartaric, *p*-toluenesulfonic acids, and the like. Particularly preferred are citric, hydrochloric, maleic, fumaric, phosphoric, sulfuric, tartaric and *p*-toluenesulfonic acids. Compounds of the invention may also  
 5 be in the form of hydrates.

5 "Halogen" is intended to include for example, F, Cl, Br and I.

The term "prodrug" refers to a chemical compound that is converted to an active agent by metabolic processes *in vivo*. [See, e.g., N. Boder and J.J. Kaminski, *Ann. Rep. Med. Chem.* 22:303 (1987) and H. Bundgaard, *Adv. Drug Delivery Rev.*, 3:39 (1989)]. The use of prodrug precursors of compounds of the present invention in any of the methods described herein is contemplated and  
10 is intended to be within the scope of the invention.

Terminology related to "protected," "protecting" and/or "deprotecting" functionalities is used throughout this application. Such terminology is well understood by persons of skill in the art and is used in the context of processes which involve sequential treatment with a series of reagents. In this context, a protecting group refers to a group which is used to mask a functionality during a  
15 process step in which it would otherwise react, but in which reaction is undesirable. The protecting group prevents reaction at that step, but may be subsequently removed to expose the original functionality. The removal or "deprotection" occurs after the completion of the reaction or reactions in which the functionality would interfere. Thus, when a sequence of reagents is specified, as it is in the processes of the invention, the person of ordinary skill can readily envision  
20 those groups that would be suitable as "protecting groups" for the functionalities involved.

In the case of the present invention, the functionalities that must be protected are amines. Suitable groups for that purpose are discussed in standard textbooks in the field of chemistry, such as Protective Groups in Organic Synthesis by T.W. Greene [John Wiley & Sons, New York, 1991], which is incorporated herein by reference. Particular attention is drawn to the chapter entitled  
25 "Protection for the Amino Group" (pages 309-405). Preferred protecting groups include BOC and Fmoc. Exemplary methods for protecting and deprotecting with these groups are found in Greene and Wuts on pages 318 and 327.

The materials upon which the syntheses described herein are performed are referred to as solid supports, beads, and resins. These terms are intended to include: (a) beads, pellets, disks,  
30 fibers, gels, or particles such as cellulose beads, pore-glass beads, silica gels, polystyrene beads optionally cross-linked with divinylbenzene and optionally grafted with polyethylene glycol, poly-

acrylamide beads, latex beads, dimethylacrylamide beads optionally cross-linked with *N,N'*-bis-acryloyl ethylene diamine, glass particles coated with hydrophobic polymer, *etc.*, *i.e.*, material having a rigid or semi-rigid surface; and (b) soluble supports such as polyethylene glycol or low molecular weight, non-cross-linked polystyrene. The solid supports may, and usually do, have functional groups such as amino, hydroxy, carboxy, or halo groups; where amino groups are the most common.

Tentagel™ NH<sub>2</sub> (Rapp Polymere, Tübingen, Germany) is a preferred amine functionalized polyethylene glycol- grafted polystyrene resin. Tentagel™-S-PHB resin has a para-hydroxy benzyl linker which can be cleaved by the use of 90% trifluoroacetic acid in dichloromethane. Techniques for functionalizing the surface of solid phases are well known in the art. Attachment of lysine to the amino groups on a bead (to increase the number of available sites) and subsequent attachment of linkers as well as further steps in a typical combinatorial synthesis are described, for example, in PCT application WO95/30642, the disclosure of which is incorporated herein by reference. In the synthesis described in WO95/30642, the linker is a photolytically cleavable linker, but the general principles of the use of a linker are well illustrated.

#### Optical Isomers - Diastereomers - Geometric Isomers

Some of the compounds described herein contain one or more asymmetric centers and may thus give rise to enantiomers, diastereomers, and other stereoisomeric forms which may be defined in terms of absolute stereochemistry as (R)- or (S)-, or as (D)- or (L)- for amino acids. The present invention is meant to include all such possible diastereomers as well as their racemic and optically pure forms. Optically active (R)- and (S)-, or (D)- and (L)- isomers may be prepared using chiral synthons or chiral reagents, or resolved using conventional techniques. When the compounds described herein contain olefinic double bonds or other centers of geometric asymmetry, and unless specified otherwise, it is intended to include both (E)- and (Z)- geometric isomers. Likewise, all tautomeric forms are intended to be included. The configuration of any carbon-carbon double bond appearing herein is selected for convenience only and is not intended to designate a particular configuration; thus a carbon-carbon double bond depicted arbitrarily herein as *trans* may be *cis*, *trans*, or a mixture of the two in any proportion.

In view of the above definitions, other chemical terms used throughout this application can be easily understood by those of skill in the art. Terms may be used alone or in any combination thereof. The preferred and more preferred chain lengths of the radicals apply to all such combinations.

# Utility

The compounds of the present invention have demonstrated utility as selective inhibitors at VLA-4 receptors. The inhibitory concentration ( $IC_{50}$ ) and the VLA-4 selectivity of test compounds for an  $\alpha 4\beta 1$  receptor using *in vitro* assays are determined in direct binding assays and competitive assays with other integrin receptors such as  $\beta 2$  (LFA-1 and Mac-1),  $\beta 3$  (GPIIb/IIIa and  $\alpha v\beta 3$ ) and  $\beta 1$  ( $\alpha 4\beta 7$ ). Compounds of the present invention have  $K_i$  values  $< 1 \mu M$ . Preferred compounds of the invention are those having  $K_i$  values  $< 300$  nM, more preferably  $< 100$  nM, even more preferably  $< 50$  nM, and most preferably,  $< 12$  nM.

Examples of preferred compounds having a  $K_i$  value  $< 50$  nM are shown below. These examples are provided by way of illustration only, and are not intended to limit the invention thereto.

#### In vitro Assays

A direct binding assay was used to quantify the inhibitory activity of the compounds. In this assay, VLA-4-expressing cells were seeded in a 96-well microtiter plate. The cells were allowed to grow for 2 days until confluent. Various concentrations of the test compound were added together with 2 nM of the europium-labeled, VCAM-IgG fusion protein. The cells were allowed to incubate at room temperature in the microwells for at least 30 minutes. Following incubation, the microwells were emptied and washed. The amount of europium-labeled VCAM-IgG fusion protein bound was determined by time-resolved fluorescence measurement. Inhibition of binding was determined by quantifying the fluorescence bound to the plate for each of the various concentrations of test compound, as well as for controls containing no test compound.

The VLA-4-expressing cells used in this assay was a CHO cell line stably transfected with the cDNA of the human  $\alpha 4$  and  $\beta 1$  subunits. Construction and maintenance of the cell line are described in the assay procedures. A VCAM IgG fusion protein containing the one to seven immunoglobulin domains of human VCAM-1 (D1D7) attached above the hinge region of an IgG1 molecule was labeled with europium chelates. The preparation and labeling of the fusion protein are described in the assay procedures.

The cell adhesion inhibitory activity of the test compound was determined by blocking the Jurkat cell attachment to the D1D7-VCAM IgG fusion protein. Jurkat cell is a human lymphocytic cell line expressing VLA-4 on cell surface. In this assay, each of the 96-well microtiter wells was coated with 75 ng of the VCAM IgG fusion protein. The wells were then blocked by the addition of 1% bovine serum albumin to remove nonspecific adhesive sites. Varying concentrations of the test compound were added together with the calcein-labeled Jurkat cells. The cells were allowed to adhere to the VCAM coated wells at room temperature for 1 hour in the dark. Following incubation, the plate was washed by immersing face down into a container filled with phosphate buffered saline. The wells were blotted dry on paper towel. Quantitation of the adhered cell was determined by fluorescence measurement. Decreased fluorescence indicated inhibition of cell adhesion by the test compound.

Specificity for  $\alpha 4\beta 1$  of each test compound among other integrin receptors, namely,  $\beta 2$  (LFA-1 and Mac-1),  $\beta 3$  (GPIIb/IIIa and  $\alpha v\beta 3$ ),  $\beta 1$  ( $\alpha 5\beta 1$ ) and  $\beta 7$  ( $\alpha 4\beta 7$ ) was examined. LFA-1 binds to ICAM-1 and mediates the emigration of leukocytes into inflammatory sites. Mac-1 binds to a number of ligands, including ICAM-1 and fibrinogen, and plays an important role in

neutrophil phagocytosis and oxygen free radical generation. GPIIb/IIIa on platelet surface binds to fibrinogen in plasma and induces platelet aggregation.  $\alpha v\beta 3$  binds to a number of extracellular matrix proteins, including vitronectin and mediates cell migration and prevents cell apoptosis.  $\alpha 4\beta 7$  shares the same ligands as VLA-4 (VCAM-1, MAdCAM-1, and fibronectin), but with different preference. This receptor is expressed on lymphoid cells and is involved in lymphocyte migration to mucosal tissues.

Assays of LFA-1, Mac-1, GPIIb/IIIa and  $\alpha v\beta 3$  involved coating the purified receptor on a 96-well microtiter plate. The specific ligands for these receptors were labeled with europium chelates. In the assays of LFA-1 and Mac-1, an ICAM-1 IgG fusion protein containing the one to five immunoglobulin domains of human ICAM-1 (D1D5) attached above the hinge region of an IgG1 molecule, was used. In the assays of GPIIb/IIIa and  $\alpha v\beta 3$ , europium-labeled fibrinogen and vitronectin, respectively, was used. The purified receptors were allowed to incubate in the wells with various concentrations of test compound, in the presence of europium-labeled ligands. Following incubation, the wells are emptied and washed. The amount of europium-labeled ligand bound was determined by time-resolved fluorescence measurement. Assay of  $\alpha 4\beta 7$  is similar to the adhesion inhibition assay of VLA-4 described above, and uses the  $\alpha 4\beta 7$ -expressing cell, RPMI-8886. A MAdCAM-1 IgG fusion protein containing the one and two immunoglobulin domains of human MAdCAM-1 and mucin-like repeat domain, is used as the corresponding ligand for  $\alpha 4\beta 7$ .

$\text{Eu}^{3+}$ -VCAM-1 IgG binding to CHO/VLA-4 cells may be determined as follows. 4B4 cells (CHO/VLA-4 cells) are distributed into each well of a 96-well microtiter plate at  $3 \times 10^4$ /well. The plate is incubated at  $37^\circ\text{C}$ , 5%  $\text{CO}_2$  for 48 hours and then washed twice with washing buffer, then blot dried.  $50 \mu\text{l}$  of the inhibitor solution diluted with assay buffer (2% DMSO final) is added to each well, followed by  $50 \mu\text{l}$  of  $\text{Eu}^{3+}$ -VCAM-1 IgG diluted with assay buffer at 2 nM. The plate is incubated at room temperature for at least 30 min. Each well is then washed four times with washing buffer and blot dried.  $100 \mu\text{l}$  of DELFIA Enhancement solution is added to each well, followed by agitation of the plate at room temperature for 5 min. Fluorescence of each sample is then measured (e.g., DELFIA Fluorometer 1234, Wallace, Inc., USA). In this assay, the washing buffer comprises 25 mM HEPES (pH 7.5), 150 mM NaCl, 1 mM  $\text{CaCl}_2$ , 1 mM  $\text{MgCl}_2$ , and 4 mM  $\text{MnCl}_2$ ; the assay buffer comprises 25 mM HEPES (pH 7.5), 150 mM NaCl, 1 mM  $\text{CaCl}_2$ , 1 mM  $\text{MgCl}_2$ , 4 mM  $\text{MnCl}_2$ , 1% BSA, and 20  $\mu\text{M}$  DTPA.

#### In Vivo Assays

The VLA-4 inhibitors may be further characterized in *in vivo* assays. One such assay examines the inhibition of eosinophil infiltration into the bronchoalveolar lavage fluid in the mouse (murine) model. In this assay, the animals are treated with cyclophosphamide on day 0. On days 2 and 14, the animals are immunized intraperitoneally with *Ascaris suum* extract. Seven days later, the animals are treated with various doses of the VLA-4 inhibitor. Shortly after drug administration, the animals are challenged with *Ascaris suum* extract by instillation into the trachea. Bronchoalveolar lavage of the animal is performed by instilling saline into the lung, 48 hours later. Total cell and eosinophil counts in the lavage are determined.

In the murine model of *Ascaris*-induced bronchial inflammation, one of the representative compounds (example number 32) inhibited eosinophil infiltration by 49% at an oral dosage of 30 mg/kg. By contrast, a representative prior art compound, 4-(*N*'-2-methylphenylurea)phenylacetyl-LDVP-OH, described in WO 97/03094, did not inhibit eosinophil infiltration (% inhibition = -2%) at an oral dosage of 50 mg/kg.

Other representative compounds were also tested in mice. The dosage, route of administration and inhibitory effect of representative compounds (hereinafter, all tested compounds are referenced by compound number provided in the Synthetic Examples) are shown in Table 5.

Mouse Bio-Assay Method

A compound was dissolved or suspended with an appropriate solvent at 1 mg/mL. Female Balb/c mice (7-9 weeks old) were given the compound orally. Blood samples were collected from the postcaval vein of the anesthetized mice after fifteen minutes. Serum was prepared and stored at -20 °C. Serum concentration of the compound was determined from inhibitory activities of the diluted serum by a direct binding assay using VLA-4-expressing cells and VCAM-IgG fusion protein. Serum concentration determined by this method correlated well with the concentration determined by LC/MS/MS methodologies. The dosage, route of administration and resulting inhibitory effect for the test compounds are shown in Table 7.

#### Binding assay of VCAM-1 to VLA-4 expressing cells

##### Preparation of VCAM IgG fusion protein

A VCAM IgG fusion protein containing the one to seven immunoglobulin domains of VCAM-1 (D1D7) ligated to the hinge (H), CH2 and CH3 regions of human IgG1 was used in the binding assay.

##### Construction of a stable cell line expressing D1D7-VCAM IgG fusion protein

An Epstein-Barr virus based, episomal plasmid containing a D1D7-VCAM IgG fusion gene under transcriptional control of the CMV promoter, was transfected into 293E human embryonic kidney cells. Stably transfected cells were selected using 250 µg/mL hygromycin in DMEM with 10% fetal calf serum. The cells secreted D1D7 VCAM IgG fusion protein into the medium cumulatively for up to 9 days.

##### Purification of D1D7 VCAM IgG fusion protein

The cells were cultured in DMEM with 10% fetal calf serum for 2 days, then changed to CCM5 medium and cultured for a further 10 days. The medium was centrifuged, filtered and then

incubated overnight with Protein A Sepharose 4. The Protein A Sepharose was washed extensively and the D1D7 VCAM IgG fusion protein bound was eluted using 100 mM citric acid, pH 3.

#### Preparation of europium labeled-D1D7 VCAM IgG fusion protein

The D1D7-VCAM IgG fusion protein, at 1 mg/mL, was dialyzed against 50 mM  
5 NaHCO<sub>3</sub>, 0.9% NaCl, pH 8.5. The fusion protein was added to one vial of europium-labeling reagent (DELFLIA labeling kit from Wallace, Gaithersburg, MD; catalog no. 1244-302) and incubated at room temperature in the dark overnight. The labeled protein was purified using a Sepharose G10 column and assayed for the europium content and protein concentration. The protein was stored at minus 80°C until used.

#### Construction of cell line expressing VLA-4 (CHO/VLA-4)

A CHO cell line stably transfected with the cDNA of  $\alpha 4$  and  $\beta 1$  was used in the binding assay. The gene for human  $\alpha 4$  was obtained from the American Type Culture Collection and recombined between the *XhoI* and *Xba* sites of the mammalian expression vector pCI-neo (Promega, Madison, WI). The  $\beta 1$  gene was amplified by PCR from human peripheral leukocyte cDNA and  
15 engineered such that the start codon was placed in the context of a consensus Kozak sequence. The gene was recombined into pCI-neo downstream of the CMV promoter and chimeric intron.

CHO-K1 cells were stably co-transfected with plasmids encoding the  $\alpha 4$  and  $\beta 1$  genes, and single cells expressing high levels of VLA-4 were selected by fluorescence cell sorting (FACS). The antibodies used in FACS analysis were: anti- $\alpha 4$ -PE conjugated (PharMingen, San  
20 Diego, CA) and anti- $\beta 1$ -FITC conjugated (Biosource, Camarillo, CA). A cell line 4B4, which expresses 400,000 and 300,000 sites/cell of the  $\alpha 4$  and  $\beta 1$  subunit, respectively, was used in the binding assay. The subunit numbers were determined by FACS analysis, using Quantum Simply Cellular microbeads (Flow Cytometry Standards Corporation, Puerto Rico) as standards. The cells were maintained in F12 medium, containing 10% fetal bovine serum, 10 mM HEPES, pH 7.5, 0.5  
25 mg/mL G418, using a 1:48 passage/week.

#### Binding Assay

The CHO/VLA-4 cells were seeded in a 96-well microtiter plate at 30,000 cells/well and incubated at 37°C, 5% CO<sub>2</sub> for 48 hours until confluent. On the day of assay, the wells were emptied and washed twice with 350  $\mu$ l of a washing buffer containing 25 mM HEPES, pH 7.5, 150  
30 mM NaCl, 1 mM MgCl<sub>2</sub>,

1 mM CaCl<sub>2</sub>, 2 mM MnCl<sub>2</sub>. The plate was then drained and blotted dry on paper towels to remove buffer.

The test compound was serially diluted in assay buffer (washing buffer together with 0.1% bovine serum albumin, 20 μM DTPA and 1% dimethylsulfoxide), in the presence of 2 nM of europium-labeled D1D7-VCAM IgG fusion protein. Final concentrations used ranged from 0.1 nM-10 μM. 50 μl aliquot of the test compound mixture was added to duplicate wells in the plate. Control wells for total binding received no test compound. Non-specific binding wells contained an anti-α4 monoclonal antibody (L25.3, Becton Dickinson, Bedford, MA).

The cells were allowed to incubate with the test compound mixture, in the presence of europium-labeled D1D7-VCAM IgG fusion protein at room temperature for at least 30 minutes. The cells were then washed three times with 350 μl of washing buffer, using a Skatron plate washer and blot dry. An 100 μl aliquot of DELFIA Enhancement solution was added to each well, followed by gentle agitation at room temperature for 10 minutes. The amount of europium-labeled VCAM-IgG fusion protein bound was determined by time-resolved fluorescence measurement (Model: Victor™, Wallac Inc., Gaithersburg, MD).

Percent binding was calculated as:  $[(F_T - F_{NS}) - (F_I - F_{NS})] / (F_T - F_{NS}) \times 100$  wherein  $F_T$  and  $F_{NS}$  is the fluorescence signal of the europium labeled D1D7-VCAM IgG fusion protein bound to cells, in the absence of test compound and containing an anti-α4 monoclonal antibody, respectively.  $F_I$  is the fluorescence in wells containing a test compound. The IC<sub>50</sub> (concentration of the inhibitor to inhibit 50% binding of VACM to CHO/VLA-4 cell) was determined by a curve fitting routine, PRIZM (GraphPad Software, Inc., San Diego, CA).

#### Adhesion of VLA-4 expressing cell to VCAM-1

This secondary functional assay was used to determine the potency of a test compound in inhibiting VLA-4 mediated cell adhesion.

#### Preparation of VCAM coated plate

A 50 μl aliquot of the D1D7-VCAM IgG fusion protein (1.5 μg/mL in phosphate buffered saline, PBS) was added to each well of a 96-well Costar flat bottom plate (Costar, Franklin Lakes, NJ, catalog no. 2580). The plate was then incubated overnight at 4°C. On the day of assay, the wells were emptied and washed twice with 350 μl of PBS. The plate was then blocked with 100 μl

of 1% bovine serum albumin (BSA, Sigma, cat# A9418) in PBS at room temperature for at least a hour.

#### Cell preparation

Jurkat cell (clone E6-1) was obtained from American Type Cultured Collection and was maintained in RPMI medium, 10 mM HEPES, pH 7.5, 1 mM sodium pyruvate, 10% FCS, using a 1:64 passage/week. Just prior to running the assay, Jurkat cells were labeled with 5  $\mu$ M of calcein-AM (Molecular Probe, Eugene, OR, catalog no. C1430) in RPMI medium, at room temperature for 30 min in the dark. Following labeling, cells were washed twice with RPMI medium and resuspended at  $1 \times 10^6$  cells/mL.

#### Cell adhesion assay

Immediately before the assay, the BSA solution was emptied from the VCAM-coated plate. The plate was then washed twice with RPMI medium. A 100  $\mu$ l aliquot of the labeled Jurkat cells was added to each well, followed by the addition of 50  $\mu$ l of the inhibitor solutions. Final inhibitor concentrations range from 1 nM to 10  $\mu$ M and each concentration was tested in triplicates. The inhibitor and cells were allowed to incubate at room temp for 1 hr in the dark. Following the incubation, the plate was immersed gently into a container filled with PBS, then inverted face down under PBS. The wells were drained and blotted dry on a layer of paper towel. A 50  $\mu$ l aliquot of 0.1% Triton X-100 was added to each well. The plate was incubated in the dark for 10 min. Adhesion of Jurkat cell was quantitated in a Millipore Cytofluor 2300 System plate reader set at 485 nM excitation and 530 nM emission. The  $IC_{50}$  (concentration of the inhibitor to inhibit 50% Jurkat cell adhesion) was determined by a curve fitting routine, PRIZM (GraphPad Software, Inc., San Diego, CA).

This resin has a para-hydroxy benzyl linker which can be cleaved by the use of 90% trifluoroacetic acid in dichloromethane. The loading for this resin varies between 0.27 and 0.30 mmol/g and is not double loaded.

5 **Example 1**

A three-necked 500 mL round-bottomed flask was charged with 200 mL of THF and NaH (1.5 g, 62.9 mmol). A solution of 1-vinyl-2-pyrrolidinone (6.9 g, 62.9 mmol) and methyl 3-iodobenzoate (15.0 g, 57.3 mmol) in THF (100 mL) was added dropwise to the flask over 15 min. After the addition was complete the reaction mixture was heated to reflux for 1 hr. The reaction vessel was allowed to cool to room temp and then 6 N HCl (100 mL) was carefully added. The reaction was concentrated *in vacuo* to remove the THF and then an additional aliquot of 6 N HCl (100 mL) was added and the reaction was refluxed for 14 hr. The reaction was quenched by the addition of NaHCO<sub>3</sub> until pH 9 and then the mixture was extracted 3x with EtOAc. The combined organics were dried over MgSO<sub>4</sub> and concentrated *in vacuo* to afford a yellow oil.

This oil was then placed in MeOH (100 mL) and cooled to minus 78 °C. NaBH<sub>4</sub> (3.5 g, 96.5) was then added portionwise and the reaction was allowed to warm to room temp over 2 hr. The reaction was quenched by the addition of 6 N HCl until acidic and then made basic by the addition of 40% aqueous NaOH. The solution was extracted 3x with CH<sub>2</sub>Cl<sub>2</sub>, the combined organics were dried over MgSO<sub>4</sub>, and then concentrated *in vacuo* to afford 11.4 g as a yellow oil.

The above amine was then Boc-protected by placing the amine in 50% dioxane:H<sub>2</sub>O (100 mL) and adding K<sub>2</sub>CO<sub>3</sub> until basic. To this solution was added Boc-anhydride (9.1 g, 41 mmol) and then allowed to stir for 14 hr at room temp. The reaction was quenched by the addition of 1 N HCl until acidic. The solution was extracted 3x with EtOAc, dried over MgSO<sub>4</sub> and concentrated *in vacuo* to afford a yellow viscous oil. The oil was chromatographed (25% EtOAc:hexanes) to afford 7.0 g A.

Hydrochloric acid (gas) was bubbled through 15.8 g (73.5 mmol) 2-bromophenylacetic

acid in 100 mL of methanol for 10 min. The resulting solution was partitioned between 100mL water and 100 mL CH<sub>2</sub>Cl<sub>2</sub>. The organic layer was dried over MgSO<sub>4</sub> and the solvent was removed under reduced pressure to give 16.8 g (73.5 mmol) of methyl-2-bromophenylacetate which was combined with 9.0 g (80.8 mmol) of 1-vinyl-2-pyrrolidinone, and 100 mL of dry THF under argon  
5 in a 250 mL round-bottomed flask.

To this flask was added 3.5 g (147 (mmol) sodium hydride (95%) and the solution was stirred for 10 min at room temp. A reflux condenser was added and the mixture was heated to reflux for 1 hr. The solution was cooled to room temp and the solvent was removed under reduced pressure. A solution of 30 mL aqueous hydrochloric acid and 50 mL water was added to the  
10 resultant mixture and was heated to reflux with no condenser until the solution temperature reached 96°C at which time a condenser was added and the solution was allowed to reflux for 16 hr. The solution was cooled to room temp, made basic with 150 mL of an aqueous solution of 40% sodium hydroxide, extracted with 3 x 125 mL CH<sub>2</sub>Cl<sub>2</sub>, and the combined organic layers were washed with a saturated aqueous solution of sodium chloride, dried over magnesium sulfate, and  
15 the solvent was removed under reduced pressure to give 15.0 g (63.0 mmol, 86%) of 2-(2-bromobenzyl)-1-pyrroline.

To a solution of 15 g (63 mmol) of 2-(2-bromobenzyl)-1-pyrroline in a solution of 80:20 methanol:aqueous acetic acid cooled to minus 78°C was added, in portions over a 15 min period, 5.3 g (140.0 mmol) sodium borohydride. The mixture was allowed to stir for 1 hr warming to  
20 room temp at which time the solvent was removed under reduced pressure, 150 mL of water was added and the solution was made basic with an aqueous solution of sodium hydroxide which was extracted 10 x 100 mL CH<sub>2</sub>Cl<sub>2</sub> which resulted in emulsions. The combined organic layers were washed with a saturated aqueous solution of sodium bicarbonate, dried over magnesium sulfate and the solvent was removed *in vacuo* to give 14.6 g (60.8 mmol, 97%) of the benzyl proline.

To a solution of 14.6 g( 60.8 mmol) of the benzyl proline in a solution of 70 mL of saturated aqueous sodium bicarbonate and 70 mL dioxane was added 15.1 g (67.0 mmol) of di-*t*-butyl-dicarbonate and the mixture was stirred for 16 hr at room temp. The solution was then partitioned between a 200 mL aqueous solution of hydrochloric acid and 200 mL ethyl acetate. The ethyl acetate layer was washed with 200 mL of a saturated aqueous solution of sodium  
25 chloride, dried over MgSO<sub>4</sub> and the solvent was removed under reduced pressure to give a residue which was purified by flash column chromatography (20%-100% ethyl acetate/hexane) to give  
30 11.5 g (33.8 mol, 56%) pure A'.

A (1.88 g, 5.0 mmol) was placed in a 100 mL round-bottomed flask and dissolved in DMF (50 mL). To this solution was added Pd(OAc)<sub>2</sub> (23 mg, 0.3 mmol), P(o-Tol)<sub>3</sub> (12 mg, 0.3 mmol), methyl acrylate (0.47 g, 5.5 mmol), and NaOAc (0.5 g, 5.5 mmol). This mixture was then heated to 80 °C for 14 hr. The reaction mixture was then cooled to room temp and 1 N HCl (100 mL) was added. The solution was then extracted 3x with EtOAc, dried over MgSO<sub>4</sub>, and then concentrated *in vacuo* to afford a brown oil. This oil was chromatographed with 25% EtOAc:hexanes to afford 1.32 g of the alkene ester as a colorless viscous oil.

The alkene ester (1.32 g, 4.1 mmol) was then subjected to hydrogenation. The alkene was placed in a Parr hydrogenation bottle, EtOAc (10 mL) and 10% Pd/C (100 mg) was added under inert atmosphere. The bottle was then pressurized with hydrogen at 45 psi and shaken for 4 hr at room temp. The solution was then filtered through celite and concentrated *in vacuo* to afford 1.29 g of the alkane ester.

The alkane ester (1.29 g, 4.0 mmol) was dissolved in THF (30 mL), MeOH (20mL), and water (10 mL) and saponified with LiOH (200 mg, 8.0 mmol). The reaction was stirred at room temp for 3 hr and then poured into 1 N HCl (50 mL). This solution was then extracted 3x with EtOAc, dried over MgSO<sub>4</sub>, and then concentrated *in vacuo* to afford 1.02 g of the alkane acid as a yellow solid.

The alkane acid (1.02 g, 3.3 mmol) was then deprotected by the addition of a 25% TFA/CH<sub>2</sub>Cl<sub>2</sub> solution and stirred for 2 hr at room temp. The resulting mixture was then concentrated *in vacuo* and immediately protected by dissolving the deprotected acid in 50% dioxane/water, adding K<sub>2</sub>CO<sub>3</sub> (1.2 g), and Fmoc-Cl (1.08 g, 4.0 mmol). This mixture was stirred at room temp for 14 hr and then poured in 1 N HCl (100 mL). The solution was then extracted 3x with EtOAc, dried over MgSO<sub>4</sub>, and then concentrated *in vacuo* to afford 495 mg 1 as a white crystalline solid.

The dried resin (500 mg, 0.14 mmol) was placed into a small shaker vessel. The vessel was then charged with 9 mL of DMF (2 mg, 0.42 mmol), DIC (102 mg, 0.84 mmol), and DMAP (17 mg, 0.14 mmol). The vessel was subsequently shaken for 16 hr at room temp. The contents were drained and the resin was washed 3x with DMF, MeOH, and CH<sub>2</sub>Cl<sub>2</sub>. The Fmoc group was then removed by the addition of 10 mL of 50% piperidine/DMF to the shaker vessel and shaking for 2 hr at room temp. The resulting amine resin was washed 3x with DMF, MeOH, and CH<sub>2</sub>Cl<sub>2</sub>.

To the above resin was added 9 mL of DMF, 4-[N'-(o-Tolylurea)]-phenylacetic acid (132 mg, 0.42 mmol), PyBroP (196 mg, 0.42 mmol), and DIEA (107 mg, 0.84 mmol). The contents were shaken for 14 hr at room temp and then drained and washed 3x with DMF, MeOH, and CH<sub>2</sub>Cl<sub>2</sub>. The compound was then cleaved from the resin and the filtrate was collected and then concentrated *in vacuo*. The resulting oil was triturated by taking up the oil in MeOH and slowly adding in Et<sub>2</sub>O until a precipitate formed. This precipitate was collected and dried *in vacuo* to afford 67 mg 1' as a white crystalline solid.

This mixture was stirred at room temp for 14 hr and then poured in 1 N HCl (100 mL). The solution was then extracted 3x with EtOAc, dried over MgSO<sub>4</sub>, and then concentrated *in vacuo* to afford 0.38 g 5 as a white crystalline solid.

The dried resin (500 mg, 0.14 mmol) was placed into a small shaker vessel. The vessel was then charged with 9 mL of DMF, **5** (173 mg, 0.42 mmol), DIC (102 mg, 0.84 mmol), and DMAP (17 mg, 0.14 mmol). The vessel was subsequently shaken for 16 hr at room temp. The contents were drained and the resin was washed 3x with DMF, MeOH, and CH<sub>2</sub>Cl<sub>2</sub>. The Fmoc group was then removed by the addition of 10 mL of 50% piperidine/DMF to the shaker vessel and shaking for 2 hr at room temp. The resulting amine resin was washed 3x with DMF, MeOH, and CH<sub>2</sub>Cl<sub>2</sub>.

To the above resin was added 9 mL of DMF, 4-[N'-(o-Tolylurea)]-phenylacetic acid (132 mg, 0.42 mmol), PyBroP (196 mg, 0.42 mmol), and DIEA (107 mg, 0.84 mmol). The contents were shaken for 14 hr at room temp and then drained and washed 3x with DMF, MeOH, and CH<sub>2</sub>Cl<sub>2</sub>. The compound was then cleaved from the resin and the filtrate was collected and then concentrated *in vacuo*. The resulting oil was triturated by taking up the oil in MeOH and slowly adding in Et<sub>2</sub>O until a precipitate formed. This precipitate was collected and dried *in vacuo* to afford 51 mg **5'** as a white crystalline material.

## A. CLASSIFICATION OF SUBJECT MATTER:

US CL :

514/253:09, 314, 343, 381, 428, 429; 544/372; 546/177, 279.1; 548/251, 540

## BOX I. OBSERVATIONS WHERE CLAIMS WERE FOUND UNSEARCHABLE

2. Where no meaningful search could be carried out, specifically:

Of the multitude of variables and their permutations and combinations (e.g., W, A, W1, R, X, M, etc. and the substituent variables thereof) result in claimed subject matter that is so broad in scope that it is rendered virtually incompressible and thus no meaningful search can be given. Note also that the claimed subject matter lacks a significant structural element qualifying as the special technical feature that clearly defines a contribution over the prior art. The subject matter claimed contains a -NH-C(A)-NH- group which does not define a contribution over the prior art. Therefore, the first discernable invention which is compounds wherein W and W1 are phenyl, A is O, R is - (CH<sub>2</sub>)<sub>n</sub>-, X is -C(O)- and M is pyrrolidinyl (i.e., the compounds found in claims 17 and 18) has been searched.
